Towards New Poverty Lines for India

HIMANSHU

This paper presents the result of an exercise prepared for the Planning Commission's Expert Group to Review the Methodology for Estimation of Poverty to draw up new poverty lines and, correspondingly, new poverty estimates based on the National Sample Survey consumption data. The exercise begins by accepting the official all-India urban poverty estimate of 25.7% for 2004-05, then derives the all-India urban poverty line that corresponds to this head count ratio by using the multiple rather than uniform reference period distribution from the NSS data. It then recalculates, based on this modified poverty line, new state-wise urban and rural poverty lines that reflect spatial variations in the cost of living in 2004-05.

The resulting estimates of the incidence of rural poverty show a head count ratio of 41.8% for 2004-05 as against the official estimate of 28.3%. The estimates reveal much larger rural-urban differences but less concentration of either rural or urban poverty in a few states. Although the new poverty lines preserve the official estimate of all-India urban poverty in 2004-05, there are significant changes at the state level.

This paper, which was presented at an workshop convened by the Planning Commission's Expert Group to Review the Methodology for Estimation of Poverty, is in turn a modified version of an original paper by Himanshu, Rinku Murgai and Abhijit Sen.

Unlike the original paper, which used median prices for the bottom 60% of population, this paper uses median prices for the entire population. Also the final cost of living indices reported here involve fewer steps than in the original paper.

These changes were made on the suggestion of the expert group and all results and diagnostics have correspondingly been recalculated. Comments by Suresh Tendulkar, R Radhakrishna, C Ravi, Kirit Parikh and participants of the workshop are gratefully acknowledged.

Himanshu (himanshu2@gmail.com) is at the Jawaharlal Nehru University and visiting fellow at Centre de Sciences Humaines, New Delhi.

This paper amplifies on a suggestion made to the committee constituted by the Planning Commission to review the existing methodology for official poverty estimation in India. In brief, the suggestion was to accept the official all-India urban poverty estimate of 25.7% for 2004-05, derive the all-India urban poverty line that corresponds to this using the multiple or mixed reference period (MRP) rather than the uniform reference period (URP) distribution, and to recalculate from this modified poverty line new state-wise urban and rural poverty lines that reflect actual spatial variations in cost of living during 2004-05.

This suggestion is based on six considerations:

First, that in light of unnecessary past controversies on the matter, it is essential to clarify that poverty in India is measured purely on the consumption dimension and that all other dimensions, including calorie norms on which present poverty lines were originally constructed, are incidental and only of historical significance.

Second, that once it is agreed that what is being measured is consumption poverty, a basic requirement for valid spatial or inter-temporal comparison of this is that poverty lines used across space and time should represent equivalent purchasing power parity (PPP) at whatever reference consumption level is taken to be the cut-off for basic minimum needs. In particular, once this reference cut-off is chosen, this should apply equally and without discrimination to all locations, rural and urban, with the only location-specific adjustment being for differences in cost of living.

Third, in order to maintain continuity of presently accepted notions of the minimum standard of living required to avoid absolute poverty, it is desirable that the reference cut-off be anchored to some aspect of present practice. There are two possible references, the present all-India urban and rural poverty lines, of which only one can be chosen since the other must be determined by actual cost of living differences.

Fourth, official rural poverty estimates are widely perceived to be too low and no longer conforming to acceptable basic needs. Since official urban poverty estimates are less controversial, our choice of reference consumption cut-off is the MRP equivalent of the present official all-India urban poverty line, which leaves measured all-India urban poverty incidence unchanged from its current official estimate.

Fifth, the relatively minor matter of choosing the MRP cut-off that gives the same urban poverty rate as official, rather than taking the present official urban poverty line directly, is because the National Sample Survey (NSS) now uses the MRP rather than URP in most of its surveys. It is necessary to have poverty lines that correspond to MRP distributions.

Sixth, although the new poverty lines are not based on any particular norm of basic needs, and are outcome of a purely technical exercise to calculate cost of living indices relevant around the present all-India urban poverty line, this choice can be defended normatively. In particular, albeit modest norms of nutrition and of paid-out education and health costs are adequately met at the all-India level and in most, although not all, states.

Cost of Living Indices

This paper reports state-wise rural and urban poverty lines obtained from a technical exercise to calculate cost of living indices relevant around this consumption norm. Based mainly on NSS unit values, this is similar to Deaton (2003) and to earlier work used by the 1993 Expert Group of the Planning Commission. However, these cover more items and treat interstate and rural-urban price differences somewhat differently. The new poverty lines correlate very well with Deaton's across states but show more urban-rural difference, mainly on account of wider coverage of non-food items. Nonetheless, we too find that existing official poverty lines exaggerate urban-rural price difference, spuriously place rural poverty as less than urban in as many as nine major states, and also correlate poorly with interstate variations in cost of living. But we differ with Deaton in his suggesting upward revision of existing rural poverty lines and hence of estimated rural poverty – from 28.3% to 41.8%.

This is because of the choice of the present official all-India urban poverty estimate as reference and the fact that urban-rural price differences are actually much less than those implicit in official poverty lines. If instead, like Deaton, we had used official all-India rural poverty as the reference, existing urban poverty estimates would be revised down while leaving all-India rural poverty levels unchanged. Consequently, although pegging new poverty lines as PPP equivalents of an existing norm avoids opening a Pandora's Box of reconsidering the cost of basic minimum needs, a normative choice different from Deaton is made here in using existing official estimates of urban, rather than rural, poverty as the reference.

As mentioned above, the urban reference was chosen since this is the less controversial of two standard of living norms below which people are currently deemed officially poor. Official rural poverty estimates are widely perceived to be too low and no longer conforming to acceptable basic needs. Critics have focused mainly on two aspects: adequacy of poverty lines to reflect nutrition need and validity of procedures to update poverty lines benchmarked far back in 1973-74. On both these there is less criticism of urban poverty lines and estimates. This is justified because although both urban and rural official poverty estimates are well below the incidence of persons falling short of original calorie norms, anthropometric estimates of urban malnutrition are close to official urban poverty estimates while independent estimates of rural malnutrition far exceed official rural poverty. Similarly, although outdated price indices have been used to update both urban and rural poverty lines, it is the Consumer Price Index-Agricultural Labourers (CPI-AL) rather than the Consumer Price Index-Industrial Workers (CPI-IW) (used for official rural and urban poverty lines respectively) that has definitely

underestimated the cost of living increase from 1973-74 benchmarks. Unlike CPI-IW, the CPI-AL weighting diagram did not include education, medical services or conveyance till 1995-96, and on fuel assumed that firewood was available free. Actual purchase prices of all of these items rose much more than of food, and their weight in expenditure of the rural poor also increased considerably because of lifestyle change towards urban consumption patterns, inadequate provision of public services and reduced access to common natural resources. Even for food, as Deaton (2008) notes himself, the CPI-AL may have underestimated actual price increase quite significantly in the more recent period, much more than CPI-IW.

Since original calorie norms are not met, we have compared actual food, education and health expenditures at reference poverty lines to some other albeit rock-bottom criteria. It turns out that average food expenditure near the official urban poverty line (and its PPP equivalent in rural) can buy an Indian Council of Medical Research (ICMR) norm diet and also exceeds the cut-off on 61st round distribution of persons by food expenditure that corresponds to National Family Health Survey-3 (NFHS-3) malnutrition (average of low body mass index (BMI) adults and underweight children). Similarly, in both urban and rural areas, actual education and health expenditures at the urban reference are adequate to send all 5-14 age children to school and meet normal (but not catastrophic) medical contingencies at what NSS reports are age-specific probabilities of disease onset and median costs of schooling and treatment. Actual food, education and medical expenditure at the present official all-India rural poverty line (and its PPP equivalent in urban areas) do not satisfy these criteria. This normative validation of the suggested reference is likely to be fairly robust to any NSS underestimation that lowers both actual consumption and criteria cut-offs by similar magnitudes.

However, it must be stressed that these normative criteria are not the *raison d'être* for the suggested poverty lines. As made clear above, this is a purely technical exercise to obtain new state-specific rural and urban poverty lines that reflect current spatial differentials in cost of living and yet remain rooted to a present measure of absolute consumption poverty. The normative criteria are used only to discriminate between official all-India urban and rural poverty lines as valid starting points for our calculations, since only one of these can be reference and the other must be determined by actual spatial price differentials. In particular, these criteria do not enter our calculation of new poverty lines; and the choice is only relative among two official standard of living references, both of which are historical and need not reflect today's norms. For example, the reference suggested is less than, although close to, the 2005 PPP \$1.25/day norm used by the World Bank in its latest world poverty estimates. Moreover, although we argue for official all-India urban poverty line as reference, and use expenditure shares corresponding to this in our calculations of spatial cost of living indices, these are quite robust to moderate changes so that poverty lines corresponding to a range of alternative references can be obtained simply by scalar multiplication. In fact, since our main exercise is to derive spatial cost of living

indices, robustness of these indices is intrinsically more important than the reference standard of living to which these are applied. For this reason, we also subject our estimates to some tests of plausibility.

The paper is organised as follows: In Section 1 we discuss the present official poverty lines, and assess the validity of criticisms made against these. Our main conclusion is that while the all-India urban poverty estimates are fairly robust to these criticisms, the rural estimates are not. In Section 2 we present our suggested new poverty lines, and the corresponding poverty estimates, along with details of the methodology used. In Section 3 we normatively evaluate our new poverty lines with respect to actual expenditures on food and on health and education near these poverty lines. We also subject our new poverty lines and estimates to some tests of robustness. These involve tests of whether our cost of living indices are really comparing like with like, and of the characteristics of those people whose poverty status is changed by the shift to new poverty lines. The paper concludes with some suggestions on how these new poverty lines may be carried forward and backward over time.

1 Current Official Poverty Lines

The current poverty lines used by the Planning Commission are based on recommendations of the Expert Group on Estimation of Proportion and Number of Poor (1993) chaired by D T Lakdawala.¹ The approach of this expert group involved four major steps. The first was to identify a norm for food expenditure. On this, the expert group relied on Recommended Dietary Allowances (RDA) from the Report of the Task Force on Projections of Minimum Needs and Effective Consumption Demand (1979): 2,400 calories per day per capita for rural areas and 2,100 calories per day per capita for urban areas. The second step was to apply these to data from the 28th round (1973-74) NSS Consumption Expenditure survey in order to obtain all-India poverty lines. Actual all-India urban and rural distributions of calorie intake of households by their monthly per capita consumption expenditure (MPCE), including non-food expenditure, were used to identify MPCE levels corresponding to the respective RDA, and all-India poverty lines were fixed at these levels. Thus, all-India poverty lines were obtained separately for rural and urban areas pegged to RDA norms for food expenditure, with an implicit allowance for non-food expenditure at actual consumption levels of people whose food consumption was near the respective RDA. By this procedure, the expert group arrived at Rs 49 per capita per month as the all-India rural poverty line and Rs 57 per capita per month as the all-India urban poverty line for 1973-74.

In the third step, state-wise poverty lines for 1973-74 were calculated from these all-India poverty lines by applying Fisher Indices of state prices relative to all-India, reported by Chatterjee and Bhattacharya (1974) for rural areas and Minhas et al (1988) for urban areas. For the fourth step, i.e., updating these state-wise poverty lines, the expert group suggested use of CPI-AL for rural areas and CPI-IW for urban,² with components of these reweighted to actual 1973-74 consumption around the all-India poverty lines and these fixed weights applied uniformly to every state. Thus,

the expert group used calorie norms *only as a peg* to derive MPCE norms with which to measure consumption poverty. It neither applied calorie norms to obtain 1973-74 state-specific poverty lines nor suggested their use to track poverty changes over time. Once all-India poverty lines were fixed using calorie norms for 1973-74, all further adjustments were only for variations in cost of living across states and over time.

However, the expert group's cost of living adjustments were partial and hybrid. Use of RDA to obtain 1973-74 all-India poverty lines separately for rural and urban meant that these did not reflect actual rural-urban price differentials. The rural and urban interstate price indices were from different sources and for different years, which made state poverty lines prone to further error. The method to update poverty lines with fixed 1973-74 weights did not allow for changes in consumption patterns. Also, some well-known data gaps were ignored, e.g., that the 1960-61 series of CPI-AL, while including firewood in its weighting diagram, treated this as available free. In addition to normative issues, particularly growing divergence from original calorie norms, these weaknesses are source of criticism of existing poverty lines.

Criticism of existing poverty lines has been both normative and technical, with the most important normative criticism being that existing poverty lines fail to preserve original calorie norms. Also, it has been argued that these provide inadequately for health and education because it was originally assumed that these services would be provided by the state (Dev and Ravi 2008). Technical criticism has focused mainly on problems of cost of living adjustment both over time and across space. Although the technical literature has largely bypassed the normative content of poverty lines, a major concern expressed is that the ratios of official urban to rural poverty lines are unrealistically large in recent years, compared to both the initial 1973-74 ratio and ratios obtained from recent NSS unit level data. This means that official poverty lines, which do not directly compare rural and urban prices, may be discriminating against the rural poor in the sense that a rural person could be classified as non-poor while an identical urban person consuming the same bundle of goods and services is classified as poor.

As far as the original calorie norms are concerned, it is a fact that there is now a huge difference between the NSS estimates of proportion of people with less calorie intake than these norms (79.8% rural and 63.9% urban in 2004-05) and the official poverty headcount (28.3% rural and 25.7% urban). However, this divergence was already evident when the expert group had submitted its report stating that "use of calorie norm in measuring poverty amounts only to a first order approximation to what may be considered to be an acceptable level of minimum need", and deciding against using direct calorie norms to measure poverty.³ The reasons for this are available in the report.⁴ But, since recent studies continue to highlight this issue, it is important to stress again that calorie norms were used only to peg reference 1973-74 all-India MPCEs from which state-wise poverty lines have been derived, then and subsequently, by applying cost of living adjustments. What was being measured was consumption poverty, not calorie deficiency.

Beyond Calorie Norms

In other words, while deficiencies in calorie intake are certainly important, this was not the dimension that either the expert group or previous Indian literature had used to measure poverty. On the dimension of consumption expenditure that was chosen, actual calorie intake is immaterial so long as norm intakes are affordable. Poverty lines, even in 1973-74, assured at best the affordability of a consumption bundle that contained food items with norm calorie content and did not classify as poor all those with less than norm calorie intake. Whether this remains true is part of the technical issues concerning subsequent cost of living adjustment. But as Pronab Sen (2005) showed, although actual calorie intake around the poverty line was well below the norm in 1999-2000, calorie norms could have been met in most states without reducing non-food expenditures if those around the poverty line had spent the same amount on food but consumed the more cereal-intensive diet of the average poor. Moreover, recent research shows that a similar conclusion continues to hold in urban areas, although not in rural, even if intake norms are expressed in terms of culturally palatable minimum cost diets that adequately meet ICMR norms of all nutrients, not just calories.⁵

The implication of the above is that the actual calorie shortfall now observed at the poverty line may be because of preference for a more varied and expensive diet and, at least in case of urban areas, is not because of lack of affordability. Nonetheless, since adequate nutrition is the most basic minimum need that poverty lines should satisfy, mere affordability of norms cannot be a convincing defence of official poverty counts if actual hunger and malnutrition at present were anything like the incidence of people with calorie intake below these norms.⁶ But this is unlikely, not only because the NSS reports negligible incidence of subjectively felt hunger, but also because the original Task Force calorie norms were almost certainly too high. For example, FAO's minimum calorie norm for India is currently 1,770 calories per capita per day,⁷ which is very close to average 61st round calorie intake of those near official poverty lines in both rural and urban areas. Although the sedentary activity levels assumed are questionable for rural areas, the fact that actual intake at the cut-off is close to the FAO norm does provide a defence at least for the official all-India urban poverty line.

However, the real lesson from all this is that calorie needs vary widely and all-India calorie norms are not the best way to define minimum nutritional need.⁸ The best indication of this is that the incidence of calorie deficiency from any all-India norm, whether original or FAO, correlate very poorly with direct anthropometric measures of malnutrition from the National Nutrition Monitoring Bureau (NNMB) and the NFHS. This is true over time (while calorie intake has declined, nutrition outcome indicators have improved); across states (e.g. Kerala and Tamil Nadu have both lower calorie intake and lower malnutrition than Bihar and Uttar Pradesh); and also between rural and urban. If incidence of inadequate nutrition is judged by the average of low BMI adults and underweight children, this was about 25% in urban areas and 40% in rural during 2005-06 (NFHS-3).⁹ On this basis, the 2004-05 official all-India rural poverty count of 28.3% does

appear to be too low, but the all-India urban poverty count of 25.7% is again defensible.

Our main conclusion from this discussion of criticisms of the nutritional adequacy of present official poverty lines is that it is confusing and also probably misleading to continue to rely on the original calorie norms.¹⁰ Critics are correct in questioning the present official estimates of rural poverty since there is strong *prima facie* evidence to suggest that this underestimates nutritional inadequacy, but this evidence also lends some support to official estimates of all-India urban poverty. Since calorie intakes correlate poorly with other indicators, and nutritional adequacy needs to be judged in a holistic manner, it is probably better to move directly to a consumption expenditure norm and judge the nutritional adequacy of this norm against data from nutrition outcome indicators. On this basis, the present all-India official urban poverty line is certainly preferable as the consumption poverty cut-off than the present official all-India rural poverty line.

This conclusion is supported by three other normative considerations:

(1) Education: In 2004-05, NSS reports that as against only about 75% of 5-14 year rural children in the official rural poverty line class attending school, nearly 90% of urban 5-14 year old children in the urban official poverty line class were attending school. In terms of expenditure, average actual expenditure on education was adequate to send all these children to school at the median cost of schooling per child.

(2) Health: In terms of expenditure on health in 2004-05, average actual expenditure on non-institutional medical care incurred by those at the urban poverty line class was slightly more than required to meet a probability of disease onset of 9% per month at the median cost of treatment per disease episode as reported in NSS 60th round. As against this, actual average expenditure on non-institutional medical care by those around the official rural poverty line was lower than required. For institutional medical care, actual expenditure by both the urban and rural poverty classes was less than required to meet a 2.5% probability of hospitalisation at the median cost of hospitalisation. However, taking both institutional and non-institutional medical care, actual expenditure of the urban poverty line class was adequate while that of the rural poverty line class was substantially less required than to meet the above probabilities at median cost.

(3) Treatment of Similar Households: Considering two groups of poorest households, those in the casual labour household type and those where the household head is illiterate, the official urban poverty line classified 58% and 53% of persons in such urban households as poor in 2004-05. However, the official rural poverty line classified as poor only 46%, 34% and 38% respectively of those in rural agricultural labour households, non-agricultural labour households and households with illiterate heads. Clearly, similar household types in urban and rural areas are being classified differently by the two poverty lines. The urban poverty lines appear more appropriate since it classifies as poor the majority of people in what are acknowledged to be the poorest groups. By

the same token, the present rural official poverty lines are somewhat suspect especially since it is difficult to believe that poverty is higher among urban casual labourers than their rural counterparts, most of whom are currently classified as non-poor.

Technical Criticisms

These observations lead into the set of technical criticisms that have primarily focused on the problem with price deflators, at interstate level, rural-urban and over time. The primary reason for the criticism has been some obvious anomalies in poverty estimates using existing poverty lines. For majority of the states, urban poverty in 2004-05 turns out to be higher than rural poverty. This is the case in some of the major states such as Andhra Pradesh, Haryana, Karnataka, Kerala, Chhattisgarh, Jammu and Kashmir, Madhya Pradesh, Maharashtra, Rajasthan and Tamil Nadu by URP poverty estimates. Orissa, Uttar Pradesh and Uttarakhand get added to the list of these states if MRP estimates are used. That is, among major states only Assam, Bihar, Jharkhand, Gujarat and West Bengal remain as states where rural poverty is higher than urban poverty. Even for all-India estimate of poverty by MRP, rural HCR is 21.8 compared to 21.7 in urban areas. While this in itself may not be problematic, it appears so given the fact that urban growth per capita has outpaced rural growth per capita, particularly in the post-liberalisation period. Similar anomalies appear as far as interstate poverty estimates are concerned (for example, urban Assam and rural Andhra Pradesh).

While some of these anomalies have their genesis in the way that the expert group of 1993 used the then available indices of interstate price differentials, these have become acute because of the deflators used to update these poverty lines. This was pointed out comprehensively by Deaton and Tarrozi (2000) and Deaton (2008). As Deaton points out, part of the reason that the CPI indices have failed to capture the true extent of inflation has been the use of outdated weights. While the share of food in consumption basket of the people around the poverty line has fallen to less than 65% in 2004-05, the poverty lines deflators still use the weights implicit in the 1973-74 distribution which is around 80%; and while 75% of rural children in the poverty line class went to school in 2004-05, this proportion in the 1970s was only around 40%. The second problem has been the movement of CPI indices for certain groups over time, e.g. firewood in CPI-AL in rural areas, and the fact that health and education costs which have increased faster than all other costs according to private final consumption expenditure (PFCE) deflators from the National Accounts Statistics (NAS) were not even monitored by the CPI-AL till the mid-1990s. Even within food, cereals prices have increased much less than non-cereals prices between 1973-74 and 2004-05, so that it is not surprising that Deaton (2008) finds underestimation also in the inflation rate of food, particularly in the rural poverty line calculations, compared to inflation rates obtained using unit values from the NSSO consumption expenditure surveys. The combination of these errors which crept in over time appears to have led to serious distortions in official poverty lines. These distortions are, moreover, much more serious in the rural poverty lines than urban, essentially because the CPI-AL had more gaps and also because rural consumption patterns have shifted more than those of the urban poor.

Most of these issues with the existing poverty lines are already in the public domain and there have been efforts to correct the poverty line of these mistakes. Two important efforts in this regard are by Martin Ravallion and Gaurav Datt at the World Bank and Angus Deaton. However, these corrections differ in how they correct the existing poverty lines. The Ravallion-Datt corrections are limited to (1) correction of some distortions created due to the use of interstate price differential for wrong years by the 1993 expert group, and (2) correction for the index of fuel and firewood in the CPI-AL using price data from labour bureau. In particular, Ravallion-Datt follow the expert group in starting with the same two different all-India poverty lines for 1973-74 and use the same price indices, i.e., the CPI-AL and CPI-IW.

Deaton Approach

Deaton's approach to correcting the poverty line is, on the other hand, substantially different from the methodology adopted by the expert group. Not only does Deaton use price data from the consumption expenditure surveys of NSSO but he also uses Fisher's index for both the interstate price differential and the rural-urban price differential. The notable point with Deaton's exercise is that he uses the rural-urban price differential to correct imbalances in poverty lines across rural and urban areas of each state. His starting point of this exercise is the 1987-88 consumption expenditure survey. But with any such exercise which uses rural-urban indices as well as interstate indices, his starting poverty line is pegged to any one poverty line. In the case of Deaton's exercise, he takes the 1987-88 all-India rural poverty line as the starting point of his calculations. This is a departure from the expert group method which uses normative bundles separately for rural and urban areas. Since his method involves use of rural-urban indices along with interstate price indices, there can be only one normative bundle in this kind of exercise. However, the real problem with Deaton's exercise is that his indices are based on unit values from the NSSO consumption expenditure surveys and therefore limited to only food items. This limitation is a crucial factor especially when the share of food in total expenditure has been declining secularly over the years. One of the important findings from Deaton's exercise was that rural-urban price differential obtained using unit values from NSS consumption expenditure surveys was only 15% (higher for urban areas) compared to roughly 40% implicit in the existing poverty lines (in 1999-2000).

However, both these corrections have avoided the issue of MRP-URP differences in consumption basket. At the same time, both these exercises are limited to correcting for the anomalies in price indices without looking at the normative aspect of the poverty line, particularly its anchoring with the calorie norm. While Ravallion's starting point is the normative poverty line taken by the expert group for 1973-74, Deaton's starting point is the rural all-India official poverty line. In that sense, both these corrections do not reject the normative poverty line suggested by the expert group.

2 New Poverty Lines for India

In light of the above criticisms and the apparent problems with the existing poverty lines, this paper proposes a new set of poverty lines. The basic approach of setting the new poverty line

is similar to the exercise attempted by Deaton. The last year for which Deaton's exercise is reported is 1999-2000. However, for all calculations in this paper we have used the consumption expenditure survey of 2004-05. Apart from the fact that the 61st round is free from all the problems of contamination (which even though does not affect unit values, is not the right survey year because of the problems inherent in budget shares), it is also the most recent quinquennial round for which the consumption expenditure data is available.

The second point of departure is that the interstate and rural-urban price indices used in the calculation of the new price indices are much more comprehensive than the indices used by Deaton which were primarily based on food prices. However, we follow the essential suggestion of Deaton of using price data from NSS surveys rather than the CPI price data. This is possible for food, fuel, clothing and footwear, which together account 75-80% of the consumption of poor. Among other items, we have used the Employment-Unemployment Survey (EUS) of NSS 61st round to create a price index for education expenditure and for the index of health expenditure we have used the 60th round NSSO survey which was focused on health expenditure. CPI indices from Saluja-Yadav's calculations for the expert group have been used only for remaining goods and services, other than rent and conveyance. Our NSS unit-based indices thus cover 90% of the consumption basket of the poor excluding rent and conveyance, and final poverty lines also use actual NSS expenditure on rent and conveyance.

The third point of departure is that we use the all-India urban poverty line of 2004-05 as the starting point of other state poverty lines in urban areas and also in rural areas. However, this is not an arbitrary choice, but is based on evidence which we present in the following section. While there is no attempt in this paper to decide new normative poverty lines either rooted in a nutritional norm or any other objective criterion and we like others take the official poverty line as our starting point, we do cross-check the suitability of the existing poverty line in capturing the poor using external indicators.

The fourth point of departure is that the budget shares used in our calculation of price indices are based on mixed recall period. This is justified in light of the fact that NSSO has already moved to the MRP reference period in its annual rounds after 1999-2000. This is likely to continue in the future and therefore any new poverty line should be based on MRP estimates of consumption expenditure rather than URP estimates which has been the practice so far.

NSSO Price Data

As with Deaton's exercise, our poverty line relies on the indices created using price data from the NSSO consumption expenditure survey, but with the 2004-05 round of consumption expenditure data. We use the price data obtained from the consumption expenditure survey for food, intoxicants, fuel, clothing and footwear. For all these items price data can be obtained from the consumption survey. However, unlike Deaton, we use median prices of each item in each state and sector. For PDS items (rice, wheat, sugar and kerosene), the prices are obtained after aggregating

the PDS and non-PDS items together. For, clothing and footwear we have used the prices obtained from the 365-day estimates of these commodities. Some items, which are insignificant in terms of their consumption share, have been dropped. The cut-off for selecting these items is Rs 0.15 per month (Rs 1.8 per year for 365-day items). If these items have lower than this consumption in six or more states out of a possible combination of 70 values (35 states and union territories for rural and urban areas each) they have been dropped. Implementation of this procedure has led to 11 items being dropped. For those states and sector where the item has been consumed by less than five households, it has been treated as not being consumed in that state.

The all-India prices are not calculated directly from the unit data but are derived from the state prices. Using state quantity shares and prices, the all-India price of each item is the weighted-average of state prices. The weights used in this case are the population weights from the census. These state-wise price and quantity data are used to obtain a Paasche index and Laspeyres index for each state relative to all-India. The geometric mean of these gives us the Fisher's index for each state relative to all-India. We repeat the same procedure to obtain urban to rural Fisher index for each state. These indices were obtained for all states including the north-eastern states. However, we have dropped union territories from the calculation at this stage.

This procedure has been used for food, fuel, clothing and footwear. For all these items and item groups, the unit values can be obtained from the NSS consumption expenditure surveys. For the education, there are no such unit values that can be used. Therefore, we have used the EUS of NSSO for obtaining the index of cost of education. For this purpose, we have calculated the cost of education per schoolgoing child in each state for rural and urban areas for children in the age-group of 5-15 from the 61st round (2004-05) of EUS. For the index of health expenditure we have used the 60th round (January-June 2004) which focuses on health expenditure. For construction of the index, we have calculated health expenditure per treatment in case of non-institutional medical care and health expenditure per case of hospitalisation for institutional medical care.

While these items together (food, fuel, clothing, footwear, education and health) cover around 85% of the consumption basket of the poor, we still require an index for the remaining items of expenditure. Major heads of expenditure for which the index cannot be computed from the NSS surveys are conveyance, rent, durables, entertainment and miscellaneous goods and services.

However, no firm price data is available for these item groups. Although price data for some of these items is collected for the purpose of construction of CPI indices, a closer look at the data suggests that these may not be free from errors on account of non-standardisation of the items of expenditure. Nonetheless, in the absence of alternative price data we use the price indices calculated using the CPI price data for these items except rent and conveyance. Using these Saluja-Yadav indices and our unit value-based indices, we create an aggregate index using all items except rent and conveyance for the states relative to all-India, as well as urban relative to rural for each state. In all, we use 23 commodity group indices and these are aggregated using the

budget shares of population around poverty line class in an iterative manner to obtain a Fisher aggregate index. Table 1 gives the final index numbers used in our calculation of poverty lines.

Table 1: Poverty Lines and Final Poverty Estimates for 2004-05

	Index Numbers		Poverty Line		Poverty HCR	
	Urban SRAI	Urban-Rural	Rural	Urban	Rural	Urban

All-India			446.7	578.8	41.8	25.7

Urban SRAI: Urban state indices relative to all-India. The index numbers reported in columns 2 and 3 are for all items excluding rent and conveyance. The poverty lines are further adjusted for state/sector specific actual expenditure on rent and conveyance by those near the poverty lines.

With these final Fisher price indices across states relative to all-India for urban areas and rural-urban indices for each state, the poverty line for each state in each sector has been arrived as follows.

(a) We start with the existing urban poverty estimate at all-India as our starting point. The existing urban poverty line is first adjusted for URP-MRP difference.¹¹ However, since our aggregate indices exclude rent and conveyance, we calculate the poverty line corresponding to the MRP distribution by obtaining the urban poverty line, which gives us the same headcount ratio (25.7%) using MRP distribution as one would obtain using the URP poverty line of Rs 538.60. The poverty line, which gives a poverty headcount of 25.7% in urban areas using MRP distribution is Rs 579. The share of rent and conveyance in total MPCE of this poverty line class is 5.3%. Excluding this share, the MRP poverty line is $\{579 \times (1 - 0.053)\}$ Rs 548.

(b) With this poverty line we arrive at the state urban poverty lines using the state relative to all-India index numbers. Since these urban poverty lines exclude rent and conveyance, we adjust these urban state poverty lines with actual share of rent and conveyance around

the poverty line class. The all-India poverty headcount ratio is the population weighted poverty headcount ratio of all states.

(c) We use the final all-India urban poverty lines excluding rent and conveyance to obtain rural poverty lines in each state using the rural to urban Fisher indices. These are then adjusted upwards using the actual share of rent and conveyance around the poverty line class to obtain the final rural poverty line for each state.

Use of Fisher Index

Note that we make extensive use of the Fisher index properties for obtaining final index numbers at the state level. Also, the procedure outlined above primarily deals with construction of price indices across rural-urban within each state and for each state relative to the all-India. It is in this sense conceptually similar to the exercise attempted by Deaton. However, the major point of departure is the choice of starting poverty line which in our case is the all-India urban poverty line unlike Deaton who started with the all-India rural poverty line.

3 An Evaluation of the New Poverty Lines

Since our methodology is substantially the same as Deaton's, it is useful to begin by identifying where we differ with him and how we defend these differences. First, the purely technical point that, unlike Deaton, we incorporate items for which Consumer Expenditure Survey (CES) unit values are not available. Does this make any difference? The answer is not much if separately for rural or urban. Across-states correlation between our poverty lines and state relative to all-India indices constructed only from items with CES unit values are 0.97 rural and 0.92 urban, and these also correlate well with Deaton's earlier results. However, our all-India urban-rural price ratio is 1.27 against 1.15 using CES unit values only, and our state-level ratios correlate less well with corresponding ratios using only unit value data (0.64). This is because the cost of services (e.g., education, health, conveyance and rent) are relatively much higher in urban than rural areas, but sometimes (e.g., health costs in Kerala and Goa) cheaper in richer states with better public provision than in poorer ones. We feel that our attempt to incorporate these in a plausible manner has improved upon using only CES unit values.

Second, the substantial normative point on which we differ with Deaton, i.e., to use the urban rather than rural all-India poverty line as the starting reference. Table 2 (p 45) compares actual food and health and education expenditure near the poverty line with some norms. We do this not only with our suggested poverty lines, using the urban reference, but also with what would be obtained if we had used the rural reference like Deaton. The norm against which actual food expenditures are judged is the actual state-wise food expenditure from the 61st round NSS when persons are ranked by their food expenditure and cut-off taken at the state-specific malnutrition rate from NFHS.¹² For both rural and urban the actual food expenditure is 6% higher than the norm at the all-India level at our poverty lines. These would have been 8% and 6% lower in rural and urban areas if we had followed Deaton in using the rural reference. For education our norm is the expenditure required at state-specific median cost of education per schoolgoing child aged 5-14 of sending all such children to school. For health

Table 2: Comparison of Actual Expenditure around Poverty Line against Normative Expenditure

Reference Poverty Line		Food		Education and Health		Calories Per Capita Per Day

AI-Rural represents the actual expenditures around the poverty line class with starting reference as the all-India rural poverty line for 2004-05. Similarly, AI-Urban represents the actual expenditures around the poverty line class with starting reference as the all-India urban poverty line for 2004-05.

we calculate the age-weighted probabilities of disease onset and hospitalisation from the age-specific data for urban areas in the 60th round and multiply these by the state-specific median cost per treatment and per hospitalisation.¹³ For all the three norms, the all-India norm is the population weighted average of states. Taken together, the all-India actual expenditure is 14% and 22% higher than the norm in rural and urban all-India with our poverty lines. These would be 15% and 21% lower than the norm if we had like Deaton used the rural reference. Clearly, this comparison of actual expenditures with norms provides very strong evidence to choose the urban reference as we do, rather than the rural reference

as used by Deaton. As far as the state-wise pattern is concerned, in 17 out of 20 major states actual food expenditure near our poverty lines is higher or equal to 95% of our norms in rural areas and this is so for 19 out of 20 major states in urban areas. For health and education, actual expenditure is 90% of norm in 12 and 10 of the 20 major states in rural and urban areas. The shortfall in almost all other cases is on hospitalisation, not education or non-institutional treatment.

As far as calorie intake is concerned, the all-India averages are 1999 and 1776 cal/day in rural and urban areas near our suggested poverty line and would be 1,840 and 1,691 cal/day with the rural reference. Although considerably less than the existing norm of 2,100 cal urban and 2,400 cal rural, it is interesting that the intake of those near our urban poverty line is almost exactly the same as the present FAO norm for India, with, as expected, a higher intake in rural areas because of higher activity. At the state level, actual calorie intake of those near our poverty lines exceeds the FAO norm in rural areas of 16 out of 20 states and in urban areas of 13. Moreover, we have checked that actual food expenditure of those near our suggested poverty lines is sufficient to afford a nutritionally balanced diet, based on the higher ICMR norms, as suggested by the National Institute of Nutrition.¹⁴ Further, the new poverty lines presented here are much more in line with outcome indicators from the NFHS on malnutrition.¹⁵ The correlation across states/sectors between NFHS malnutrition indicators and headcount poverty using the new poverty lines is 0.87, as against 0.5 with the official Planning Commission poverty estimates. Scatter plots of existing official and the new poverty headcounts against NFHS malnutrition indicators are presented in Charts 1 and 2.

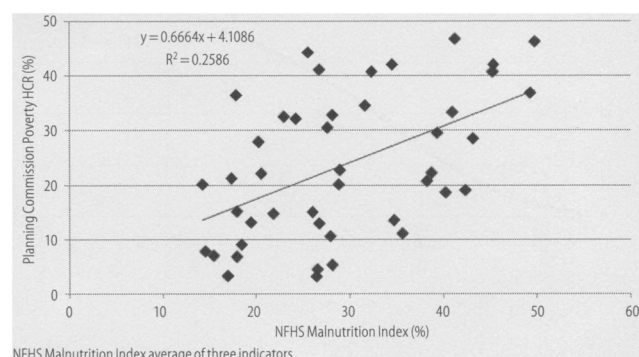

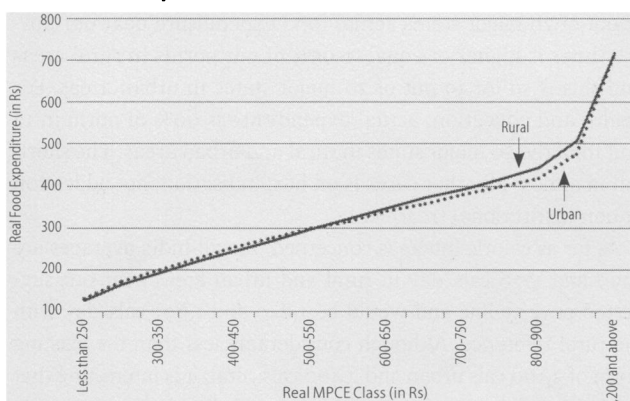

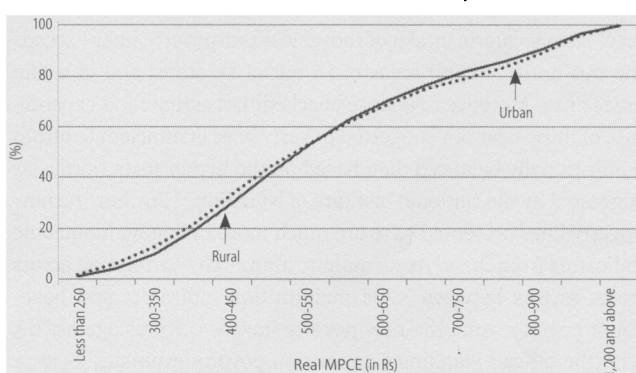

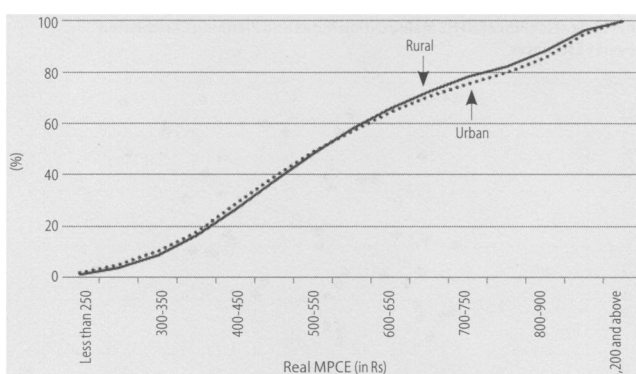

Chart 1: Scatter Plot of NFHS Malnutrition Index and Planning Commission Poverty Estimates**Chart 2: Scatter Plot of NFHS Malnutrition Index and New Poverty Estimates**

Chart 3: Real Food Expenditure at Real MPCE Class**Chart 4: Cumulative Distribution of Casual Labour Households by Real MPCE Class****Chart 5: Cumulative Distribution of Illiterate Households Head by Real MPCE Class**

Thus the choice of the all-India urban reference rather than the all-India rural reference used by Deaton is normatively justified, except possibly that it still does not meet catastrophic medical contingencies leading to hospitalisation. To have used the all-India rural poverty line as reference would have meant falling below the norm on food, health and education in the vast majority of states. Moreover, it may be noticed that the norms we use are also immune to the criticism made (for example, by Surjit Bhalla) that poverty is overestimated because of NSS underestimation of consumption. Since, our food norm is the cut-off on NSS food distribution corresponding to NFHS malnutrition; this would itself be an underestimate if the NSS food consumption is underestimated. Similarly, our health and education norms accept NSS expenditure per treatment and per schoolgoing child

and simply impose 100% school attendances and the ability to meet some probabilities of disease onset. Again, any underestimation in NSS would lead to an underestimation of norms. For this reason, our estimates appear to be normatively superior to Deaton's and also immune to the charge of NSS underestimation.

We turn now to some tests of robustness. First, when plotted against per capita real MPCE, per capita real food expenditure is almost identical for rural and urban households over a fairly wide range of real per capita MPCE (Chart 3). Real food expenditure here is nominal food expenditure of each household deflated by our indices of food prices from CES unit values. Similarly, real MPCE is the nominal MPCE of each household deflated by the deflators implicit in the final rural and urban poverty lines assuming all-India urban to be 100. This means that rural and urban real food shares are similar at similar levels of real MPCE, making our rural-urban comparisons quite robust within this range. Second, we consider the case of poor household groups. It may be seen from Charts 4 and 5 that cumulative distributions by real MPCE (nominal MPCE deflated by our cost of living indices) of two clearly poor groups (those in casual labour households and those in households with an illiterate head) are almost identical in rural and urban areas (Charts 4 and 5). Thus, urban or rural residence does not significantly affect the probability of being poor for these groups. This corrects the implausible implication of the current official estimates: that poverty among these groups is much more in urban than in rural areas. Both observations suggest that it is indeed possible to have a common yardstick to measure consumption poverty without discriminating between urban and rural, and that our cost of living indices provides this much better than the present official poverty lines.

Finally, since any change in poverty lines from those used currently involves reclassifying the poverty status of some persons, do the proposed poverty lines reclassify households in the proper direction? We examine this at household level for some characteristics – household type, education status of household head, possession of luxuries, per capita calorie intake and the food and fuel share in total nominal household consumption – of four groups: those unambiguously poor (i.e., poor by present official classification and by new poverty lines), those who get reclassified from non-poor in official to poor by new lines, those who get reclassified from poor to non-poor, and those unambiguously non-poor. Of these, the change in status is only for those who get classified as non-poor by the official method but are poor by our method (nonpoor_poor) and those who were poor by the official method but are now characterised as non-poor by our method (poor_nonpoor). There is no change in status for the two remaining groups; poor_poor and nonpoor_nonpoor. If our poverty lines reclassify the households in the right direction then we expect the nonpoor_poor to have similar characteristics as that of the poor_poor while the characteristics of the poor_nonpoor will be closer to that of the nonpoor_nonpoor. For household type and education of household head we expect a lower share among the non-poor compared to the poor; similarly, for the share of food in total consumption which is lower for the non-poor compared to the poor. On the other hand, the percentage of households possessing luxury goods is higher for

the non-poor compared to the poor. For per capita calorie intake, we expect non-poor households to have a higher calorie intake than the poor households.

In almost all cases those whom our poverty lines reclassify from non-poor to poor (nonpoor_poor) are on the average worse-off (poorer) by these characteristics than those reclassified from

mainly because our estimates are more than double in eight states (Andhra Pradesh, Gujarat, Delhi, Himachal Pradesh, Jammu and Kashmir, Karnataka, Punjab and Rajasthan) all with relatively low official poverty. An important consequence of this is that we report no case of a state having higher urban poverty incidence than rural, unlike official estimates that show higher urban

Table 3: Characteristics of Households by Alternative Poverty Lines

Categories	Percentage of Households in Each Group					
	Household Type		Education of HH Head		Possess	Share of Food
	Casual Labour	Casual Labour and Self-Employed in Non-Farm	Illiterates	Illiterates and Literates Up to Primary	Luxury Goods	in Total Consumption
Rural						
Poor_Poor	51.7	65.7	60.4	84.8	1.3	63.0
Nonpoor_Poor	46.3	61.3	53.5	79.9	3.2	62.3
Poor_Nonpoor	27.1	39.6	44.3	75.5	5.6	46.4
Nonpoor_Nonpoor	25.2	43.3	35.8	62.8	19.0	56.6
Urban						
Poor_Poor	28.6	73.78	43.6	73.2	6.7	59.1
Nonpoor_Poor	18.3	70.56	31.3	69.6	14.1	58.3
Poor_Nonpoor	15.9	61.86	28.7	53.9	22.0	50.3
Nonpoor_Nonpoor	6.2	48.11	11.9	29.9	56.2	44.8

The category before the under-stroke () is the status of the household by existing official poverty line of the Planning Commission and the category after the under-stroke is the status of the households by our poverty lines. For example, Nonpoor_Poor category of households was non-poor using the existing official poverty line but is poor by the new poverty lines.

poor to non-poor (poor_nonpoor). Moreover, on basis of these characteristics, those reclassified from non-poor to poor are much closer to those unambiguously poor than those unambiguously non-poor. Interestingly, it is only for calorie intakes that the new poverty lines may reclassify incorrectly in both rural and urban areas, suggesting that calorie intake has a very weak link with all other poverty indicators. Nonetheless, although these characteristics are not necessarily the best proxies for consumption poverty and our findings less firm on some of these than others, this analysis and comparison with NFHS data on malnutrition by states/sectors does provide independent and fairly strong support for shifting from existing official poverty lines and poverty estimates to the alternative suggested at the outset of this article.

Conclusions

If this suggestion is accepted, some major modifications will be necessary both in estimates of poverty incidence across states/sectors and on how to carry these forward and backward over time.¹⁶ As for poverty estimates, the most important difference with official estimates is that, like Deaton's earlier estimate, our estimates show a much larger rural-urban difference but less concentration of either rural or urban poverty in a few states. Although construction of our new poverty lines preserves the official estimate of all-India urban poverty incidence in 2004-05, there are significant changes at the state level. Andhra Pradesh, Chhattisgarh, Delhi, Karnataka, Kerala, Madhya Pradesh, Maharashtra, Orissa, Rajasthan, Tamil Nadu and Uttarakhand (accounting for 69% of urban poor by official estimates) show less poverty with our poverty lines while other states, particularly north-east states, show more. As a result, the interstate coefficient of variation in urban poverty falls from 0.75 by official estimates to 0.41 with our poverty lines. Our rural poverty estimates are higher than the official in almost every major state; and again interstate coefficient of variation in this is lower,

poverty than rural in a number of states. However, the broad clustering of states by high poverty (Bihar, Chhattisgarh, Jharkhand, Madhya Pradesh and Orissa), low poverty (Haryana, Himachal Pradesh, Jammu and Kashmir, Kerala and Punjab) and the rest remains unchanged.

On how to carry these new poverty lines forward, there are two alternatives consistent with the method used here. The first is to carry forward the new state/sector-specific poverty lines with state/sector-specific inflation indices derived as far as possible from NSS unit values, and using CPI-AL/CPI-IW only for commodity groups where unit values are not available. The state/sector-specific commodity group weights could either be those from the actual consumption

pattern near each poverty line group from the previous NSS large sample or Fisher indices could be used to combine weights from both the previous and current NSS round. The second method would be to carry forward only the all-India urban poverty line in this manner, and then derive state/sector-specific poverty lines corresponding to this by using current commodity group weights and spatial indices, as is done for 2004-05 in calculations for this paper. The advantage of the first method is that this would preserve the current practice of deriving all-India lines from state-specific lines obtained by updating these independently. The second method does not do this, so inflation factors could differ, but has the advantage that spatial differences in poverty lines would be based entirely on current prices and weights, and thus be more up to date. The second method would be closer to the approach followed in this paper. These alternatives can also be used to carry poverty lines backward, although additional complications would arise since NSS unit values are available only from 1983 and URP and MRP measures in earlier rounds involve different weights. This paper does not provide past estimates, but the actual past decline in rural consumption poverty was clearly less than official, in part because of deficiencies of the CPI-AL and in part because the present method has not captured actual changes in consumption patterns over time.

NOTES

- 1 For a history of setting of poverty lines in India, see Srinivasan (2007).
- 2 For urban areas, the Expert Group had actually suggested use of both CPI-IW and CPIUNME. However, the use of CPIUNME was not accepted by the government.
- 3 The expert group also looked at the hunger criterion and food share criterion along with calorie norms.
- 4 Some of these recommendations were also reported in Dev (2005).
- 5 Mahal and Karan (2007) calculate "culturally palatable" minimum cost diets that meet ICMR RDAs on energy, proteins, fats and eight micronutrients for 16 major Indian states in 1993-94 and 1999-2000, and report the percentage of population who are poor by this dietary adequacy measure if food share in total expenditure is maintained at actual levels. They find that dietary poverty by this definition is marginally lower than official poverty at the level of all-India urban, with states roughly equally divided on which urban poverty measure is

- higher. On the other hand, they report that dietary poverty exceeds official poverty in rural areas of almost all states in both years and the excess averages 8-10 percentage points at all-India level.
- 6 See Utsa Patnaik (2007) for an influential critique of the present methodology.
 - 7 The norm used by FAO for India in its State of Food Insecurity Report (SOFI) 2008 is 1,770 calories per day, down from 1,820 calories per day used in SOFI 2006. These current FAO norms follow from an ongoing joint WHO/FAO consultation. In 1985, FAO shifted from its then current RDA for calories to Estimated Average Requirements (EAR). The earlier RDA had sought to ensure that, given normal variation across individuals, requirements were met for at least 95% of population. Since this overestimates requirements for most of the population and in case of calories could exceed desirable maximum levels for many, EAR is based on the requirement at the median of the distribution. In 2004, WHO/FAO reduced the EAR further based on new data. These revisions apply to all countries not just India. For example, FAO's norm for China is now 1,900 calories, which is higher than the India norm only because its demographic composition has more adults.
 - 8 Calorie requirement depends on age, sex, weight, height, activity pattern, climate, water quality and various other factors, and RDA norms are available by the first four of these. The 1979 Task Force took average all-India data from 1971 census, but the resultant need not be RDA for any state. For example, calorie intake in Kerala and Tamil Nadu are lowest in every NSS survey, but independent data on health status and nutrition from NFHS/NNMB repeatedly show these states to be among the best states. The expert group recognised that RDA exercise was best done at state level but, since they were not recommending calorie-based poverty lines, accepted all-India RDAs from the Task Force as reference for consumption poverty.
 - 9 According to NFHS-3, urban malnutrition was 36.3% in terms of underweight children, 19.8% in terms of adult women with low BMI and 17.5% in terms of adult men with low BMI. The corresponding figures for rural areas were 49%, 38.8% and 33.1%.
 - 10 Deaton and Dreze (2009) have analysed the calorie puzzle in detail and have arrived at a similar conclusion.
 - 11 The poverty estimate of 25.7% for urban areas is based on the size distribution of households in ascending order of per capita total (consumer) expenditure (PCTE for short) on the basis of the URP. The MRP equivalent poverty line is that level of PCTE which is obtained when population is ranked in ascending order of size of MRP-based PCTE and the percentage of poor equals 25.7%.
 - 12 Average of the proportion of underweight children below five years of age and proportion of men and women aged 15-49 years with low body mass index is taken to be an aggregate outcome indicator of malnutrition. When estimated (rural/urban/state) population from NSS is ranked according to ascending size of food expenditure per capita, normative food expenditure per capita is defined by that level of food expenditure per capita that corresponds to cumulative share of population from NSS that equals the index of malnutrition derived from NFHS-3 for that state.
 - 13 We use the age-specific PAP (persons reporting ailment) in the last 15 days for non-institutional medical expenditure hospitalisation by state from the 60th round (January-June 2004). Weighted by the age-specific population distribution these give us the probabilities of disease onset and hospitalisation by state and sector. To arrive at the norm, we multiply these by the median cost of expenditure assuming everybody is treated. That is, our norm is the expected expenditure of treating all persons given the probabilities of disease onset and hospitalisation.
 - 14 National Institute of Nutrition recommends dietary intakes by age-sex and activity status for Indians. This diet weighted by actual age-sex composition for a person doing moderate work is affordable without cutting non-food expenditure by those at our poverty lines for majority states as well as in all-India.
 - 15 NFHS malnutrition indicators referred here is the simple average of three indicators; percentage of children under age 3 who are underweight, percentage of men with low BMI and percentage of women with low BMI.
 - 16 These suggestions and the proposed methodology were discussed in its meetings by the Expert Group and were subsequently accepted. The final poverty line and the poverty estimates reported in this paper are the same as reported in the final report of the expert group submitted to the Planning Commission.
